RETURN THIS SET
OF PROOF TO
PROVIDENCE

ON UNIQUENESS SETS FOR AREALLY MEAN p-VALENT FUNCTIONS

ENRIQUE VILLAMOR

(Communicated by Clifford J. Earle, Jr.)

ABSTRACT. We study the sets of uniqueness of areally mean p-valent functions in the unit disc. Namely, if $f(z)$ is in this class and has the same angular limit in a set E on the boundary of the unit disc, we prove that if p is small compared to the size of E then $f(z)$ is constant. We then construct an areally mean p-valent function which shows that some condition on the size of the set E must be imposed.

INTRODUCTION

The original F. and M. Riesz Theorem states that if a bounded analytic function in the unit disc Δ has the same radial limit in a set of positive Lebesgue measure E in $\partial\Delta$ then the function has to be constant.

Beurling [1, 3] showed that if we consider the class of univalent functions in the unit disc, the same result holds if we replace a set of positive Lebesgue measure by a set of positive logarithmic capacity in $\partial\Delta$.

We start by giving the definition of areally mean p-valent functions.

Definition 1. Let $f(x)$ be a regular nonconstant function in Δ. Define

$$n(w) = n(w, \Delta, f)$$

to be the number of roots of the equation $f(x) = w$ in Δ, and write

$$p(R) = p(R, \Delta, f) = \frac{1}{2\pi}\int_0^{2\pi} n(Re^{i\theta})\,d\theta.$$

Then if there exists a positive number p such that

$$\int_0^R p(\rho)2\rho\,d\rho \leq pR^2$$

for all positive R, we say that the function $f(z)$ is an areally mean p-valent function.

From now on we are going to denote this class of functions by AMP. This class has been studied by several authors; good references are Hayman [5] and Eke [4].

Let us consider now the following class of functions.

Received by the editors December 3, 1990 and, in revised form, March 18, 1993.
1991 *Mathematics Subject Classification.* Primary 30C45.
Key words and phrases. Areally mean p-valent, logarithmic capacity.

Definition 2. Let $f(x)$ be a regular function in the unit disc. If

$$\iint_{\Delta} \frac{|f'(z)|^2}{[1+|f(z)|^2]^2}\, dx\, dy < \infty,$$

we say that $f(z) \in D_S$. These functions are called functions of finite spherical area.

It is not difficult to show that $\mathrm{AMP} \subset D_S$. Beurling [1] proved the following theorem.

Theorem A. *Suppose that* $f(x) \in D_S$ *and that*

$$f(e^{i\theta}) = \lim_{r\to 1} f(re^{i\theta}) = \alpha,$$

whenever $e^{i\theta} \in E$, *where* $E \subset \partial\Delta$.

We define

$$\delta_\rho(\alpha) = \{w : |w-\alpha| < \rho\},$$
$$\Delta_\rho(\alpha) = f^{-1}(\delta_\rho(\alpha)) = \{z \in \Delta : |f(z)-\alpha| < \rho\},$$

and

$$\iint_{\Delta_\rho(\alpha)} \frac{|f'(z)|^2}{[1+|f(z)|^2]^2}\, dx\, dy = A_\rho(\alpha).$$

If now $\mathrm{cap}(E) > 0$ *and* $\limsup_{\rho\to 0}[\frac{A_\rho(\alpha)}{\rho^2}] < \infty$, *then* $f(z)$ *is constant*

Later Tsuji [9] gave a modified version of this theorem.

Carleson [2] proved that some condition on the limiting value α must be imposed if we want to obtain a uniqueness result for the class D_S. He constructed a nonconstant function $f(z) \in D_S$ such that $\lim_{r\to 1} f(re^{i\theta}) = 0$ for all $e^{i\theta} \in E \subset \partial\Delta$, and $\mathrm{cap}(E) > 0$.

Functions of finite spherical area are only apparently more general than those in AMP. A function f belongs to D_S if and only if some bilinear transform $\frac{af+b}{cf+d}$ for suitable a, b, c, d belongs to AMP (possibly as a meromorphic function). For AMP 0 and ∞ are special points, while D_S is invariant under bilinear transforms.

Due to the above remarks and using Carleson's construction in [2], we shall construct a nonconstant function $f(z)$ in AMP for some p, such that $f(z)$ has the same angular limit in a set of positive capacity.

In the positive direction we will prove that if $f(z)$ in AMP has the same nontangential limit in a set E of positive capacity and if p is small compared to the size of E, then $f(z)$ is constant. We will have to make precise the above statement in Theorem 1.

We start with some preliminaries. Let $f(z)$ be in AMP, such that $\lim_{z\to e^{i\theta}} f(z) = \alpha$ nontangentially for all $e^{i\theta} \in E$ and $\mathrm{cap}(E) > 0$. Now we want to reduce the problem to the case in which $f(z)$ is zerofree in some simply connected domain $\Omega \subset \Delta$. It is known [5] that any areally mean p-valent function can have at most p zeros counting multiplicity. Let z_j, $j = 1, \dots, k$ be the points for which $f(z_j) = 0$. We define $r_0 = \max_{1\le j\le k} |z_j|$. Let Ω be the simply connected domain given by

$$\Omega = \{z : r_0 < |z_j| < 1,\ |\arg z| < \pi\}.$$

le ital

Then $f(z)$ is areally mean p-valent in Ω, $f(z) \neq 0$, and $f(z)$ has the same nontangential limit α on E, where $E \subset \partial\Omega$ and $\operatorname{cap}(E) > 0$.

Then for each positive integer n, $g(z) = f^{1/n}(z)$ is single valued and $\alpha^{1/n}$ might take n different values. We call these values $\alpha_{i,n}$, $i = 1, \ldots, n$. Let $E_{i,n} \subset E$, $i = 1, \ldots, n$, be the set such that $\lim_{z \to e^{i\theta}} g(z) = \alpha_{i,n}$ for any $e^{i\theta} \in E_{i,n}$. It is clear that $E = \bigcup_{i=1}^{n} E_{i,n}$ and the $E_{i,n}$ are disjoint. Since $\operatorname{cap}(E) > 0$, there exists at least one $i \in \{1, \ldots, n\}$ such that $\operatorname{cap}(E_{i,n}) > 0$. Among those, we choose $E_{i_0,n}$ with the property that,

$$\operatorname{cap}(E_{i_0,n}) = \max_{1 \le i \le n} \operatorname{cap}(E_{i,n}) > 0.$$

Let $\gamma(E_{i_0,n})$ be the Robin constant of the set $E_{i_0,n}$.

Let $f(z)$ in AMP be zerofree, let $0 < \lambda < 1$, recall that $2\pi p(R, f)$ is the total variation of $\arg f$ on the level curves $|f(z)| = R$; then $p(R^\lambda, f^\lambda) = \lambda p(R, f)$. We want to show that the function $f^\lambda(z)$ is areally mean $p\lambda$-valent. Thus, we have to show that, and ← space #

$$\int_0^{R^\lambda} p(t, g)\, dt^2 \le p\lambda R^{2\lambda}$$

for any positive R, or

$$\int_0^{R} p(s^\lambda, f^\lambda)\, d(s^{2\lambda}) \le p\lambda R^{2\lambda},$$

or, which is the same,

$$\int_0^{R} \lambda^2 p(s, f) 2 s^{2\lambda - 1}\, ds \le p\lambda R^{2\lambda}.$$

We write $W(R) = 2\int_0^R p(s, f) s\, ds$ so that, since $f \in$ AMP, $W(R) \le pR^2$. Then for $0 < \lambda < 1$

$$\begin{aligned}
\int_0^R p(s, f) 2 s^{2\lambda-1}\, ds &= \int_0^R s^{2\lambda-2}\, dW(s) \\
&= R^{2\lambda-2} W(R) + (2 - 2\lambda) \int_0^R W(s) s^{2\lambda-3}\, ds \\
&\le R^{2\lambda-2} W(R) + (2 - 2\lambda) \int_0^R p s^{2\lambda-1}\, ds \\
&\le pR^{2\lambda}\left[1 + \frac{2-2\lambda}{2\lambda}\right] = \frac{p}{\lambda} R^{2\lambda}.
\end{aligned}$$

Multiplying by λ^2, we obtain that

$$\int_0^{R^\lambda} p(t, g)\, dt^2 \le p\lambda R^{2\lambda}$$

for any positive R, as we wanted to show.

After these preliminaries we state our theorem.

Theorem 1. *Suppose that $f(z) \in$ AMP and that*

$$f(e^{i\theta}) = \lim_{r \to 1} f(re^{i\theta}) = \alpha$$

for any $e^{i\theta} \in E$, *where* $\operatorname{cap}(E) > 0$. *Then, if*

$$\liminf_{n\to\infty}\left[\frac{\gamma(E_{i_0,n})}{n}\right] < \frac{1}{4\pi^2 p},$$

the function $f(z)$ *is constant.*

The natural question to ask is how sharp is our theorem. Namely, for fixed p is it true that for any positive ε there exists a nonconstant function $f(z) \in \mathrm{AMP}$ such that

$$f(e^{i\theta}) = \lim_{r\to 1} f(re^{i\theta}) = \alpha$$

for every $e^{i\theta} \in E$, where $\operatorname{cap}(E) > 0$, and such that

$$\liminf_{n\to\infty}\left[\frac{\gamma(E_{i_0,n})}{n}\right] > \frac{1}{4\pi^2 p} - \varepsilon?$$

1. Proofs

Proof of Theorem 1. The case $\alpha = 0$ is trivial, since then for $f(z) \in \mathrm{AMP}$ the value $\alpha = 0$ will satisfy the hypothesis of Theorem A. The case $\alpha = \infty$ can be treated in the same way by considering the function $g(z) = \frac{1}{f(z)}$, which is in the class D_S. The function $g(z)$ satisfies the hypotheses of Theorem A for the value $\alpha = 0$. Therefore, we can assume that $\alpha \neq 0, \infty$.

Suppose that there exists a function $f(z)$ such that $f(z) \in \mathrm{AMP}$ and

$$\lim_{r\to 1} f(re^{i\theta}) = \alpha,$$

when $e^{i\theta} \in E$, where $\operatorname{cap}(E) > 0$.

By a result in [8], if $f(z) \in \mathrm{AMP}$, thus $f(z) \in D_S$, then $f(z)$ is normal. Hence by a theorem in [7], if $f(z)$ is normal, radial limits of $f(z)$ are also nontangential limits.

By the observation we made in the introduction, we can assume that $f(z)$ is areally mean p-valent in $\Omega = \{z : r_0 < |z| < 1,\ |\arg z| < \pi\}$, $f(z) \neq 0$, and $f(z)$ has the same nontangential limit α on E, where $E \subset \partial\Omega$ and $\operatorname{cap}(E) > 0$.

The function $g(z) = f^{1/n}(z)$ is areally mean $\frac{p}{n}$-valent. For fixed n, choose i_0 as in the introduction. We have that

$$\iint_{\Delta_\rho(\alpha_{i_0,n})} |g'(z)|^2\,dx\,dy \le \iint_{\Omega_\rho(\alpha_{i_0,n})} |g'(z)|^2\,dx\,dy \le \frac{p\pi}{n}[\rho + |\alpha|^{1/n}]^2,$$

where $\Delta_\rho(\alpha_{i_0,n}) = \{z \in \Omega : |g(z) - \alpha_{i_0,n}| < \rho\}$, since $\Delta_\rho(\alpha_{i_0,n}) \subset \{z \in \Omega : |g(z)| < \rho + |\alpha_{i_0,n}|\} = \Omega_\rho(\alpha_{i_0,n})$; observe that $|\alpha_{i_0,n}| = |\alpha|^{1/n}$.

Let τ be a small positive number to be determined later, which is going to depend only on the function $f(z)$. Considering $\tau^{1/n} = \rho$ in the above inequalities we obtain

$$\iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})} |g'(z)|^2\,dx\,dy \le \iint_{\Omega_{\tau^{1/n}}(\alpha_{i_0,n})} |g'(z)|^2\,dx\,dy \le \frac{p\pi}{n}[\tau^{1/n} + |\alpha|^{1/n}]^2. \tag{1.1}$$

Without loss of generality we can assume that the set $E_{i_0,n}$ is closed. Then there exists a distribution $\mu(\zeta)$ of total mass 1 on $E_{i_0,n}$ such that the potential

$$u(z) = \int_{E_{i_0,n}} \log\left|\frac{1}{z-\zeta}\right| d\mu(\zeta)$$

is bounded by $V_0(E_{i_0,n}) = \gamma(E_{i_0,n})$ for any z in the complex plane. Standard computations [3, pp. 58–59] show that

$$\iint_{|z|<1} \left[\frac{\partial u}{\partial r}\right]^2 r\,dr\,d\theta \le \frac{\pi}{2}\,[\gamma(E_{i_0,n})] < \infty. \tag{1.2}$$

Define

$$S_n = \iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})} |g'(z)|\frac{\partial u}{\partial r} r\,dr\,d\theta.$$

By the Schwarz's inequality, (1.1) and (1.2)

$$S_n \le \pi\left[\frac{p(\gamma(E_{i_0,n}))}{2n}\right]^{1/2}[\tau^{1/n} + |\alpha|^{1/n}]. \tag{1.3}$$

Define now

$$\sigma_n(\zeta) = -\iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})} |g'(z)|\,d[\arg(re^{i\theta} - \zeta)]\,dr$$

for $z = re^{i\theta}$. The Cauchy-Riemann equations for the function $u(z)$ give us that

$$\frac{\partial u}{\partial r} r\,d\theta = -\int_{E_{i_0,n}} d[\arg(re^{i\theta} - \zeta)]\,d\mu(\zeta).$$

Therefore, we can write

$$S_n = \int_{E_{i_0,n}} \sigma_n(\zeta)\,d\mu(\zeta).$$

Our goal is to get an estimate of $\sigma_n(\zeta)$ from below for any $\zeta \in E_{i_0,n}$.

By the above remarks it is enough to estimate $\sigma_n(\zeta)$ at one point of $E_{i_0,n}$, since the same estimate will hold at any other point of $E_{i_0,n}$. We can assume that $\zeta = 1$ is in $E_{i_0,n}$, and hence we have to estimate

$$\sigma_n(1) = -\iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})} |g'(z)|\,d[\arg(re^{i\theta} - 1)]\,dr.$$

For $-\frac{\pi}{2} < t < \frac{\pi}{2}$ we define l_t to be a rectilinear segment of length $\cos t$ lying in $|z| < 1$ and making an angle t at $\zeta = 1$ with the radius drawn to $\zeta = 1$. Call $\tilde{t} = -\arg(re^{i\theta} - 1)$; then we have

$$\sigma_n(1) = \iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})} |g'(z)|\,d\tilde{t}\,dr.$$

We know that $\lim_{z\to 1} g(z) = \alpha_{i_0,n}$ in any angular domain. Let $\omega = \tilde{\omega} \cap \{z : |z - \frac{1}{2}| < \frac{1}{2}\}$ be the angular domain resulting of the intersection of an angular domain $\tilde{\omega}$ which has its vertex at $\zeta = 1$ and is symmetrical to the radius of $|z| = 1$ through $\zeta = 1$ and is of aperture $\frac{\pi}{2}$, with the disc $\{z : z - \frac{1}{2}| < \frac{1}{2}\}$. Then the part of ω in the vicinity of $\zeta = 1$ belongs to $\Delta_{\tau^{1/n}}(\alpha_{i_0,n})$.

Let Δ denote the common part of $\Delta_{\tau^{1/n}}(\alpha_{i_0,n})$ and this angular domain ω. Observe that $\Delta_{\tau^{1/n}}(\alpha_{i_0,n}) = \{z \in \Omega : |f^{1/n}(z) - \alpha_{i_0,n}| < \tau^{1/n}\} \subset \{z \in \Omega : |f(z) - \alpha| < \tau\}$; therefore, for τ small enough depending only on the function $f(z)$, the connected component of Δ with the point $\zeta = 1$ as boundary point lies inside the circle $|z - \frac{3}{4}| = \frac{1}{4}$. Hence,

$$\sigma_n(1) = \iint_\Delta |g'(z)|\, d\tilde{t}\, dr + \iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})\setminus\Delta} |g'(z)|\, d\tilde{t}\, dr = \mathrm{I} + \mathrm{II}.$$

Consider the range where $d\tilde{t} < 0$ in II, and call the corresponding integral III. Then

$$\sigma_n(1) = \mathrm{I} - |\mathrm{III}|.$$

By the definition of $\tilde{t}$

$$\frac{d\tilde{t}}{d\theta} = \frac{r\cos\theta - r^2}{1 + r^2 - 2r\cos\theta}.$$

Fix $r = \cos\theta_0$ so that the point $z = re^{i\theta}$ lies outside the circle $|z - \frac{1}{2}| = \frac{1}{2}$ (i.e., $r = \cos\theta$) whenever $\theta_0 \le |\theta| \le \pi$. We observe that $d\tilde{t} \ge 0$ for $|\theta| \le \theta_0$ and $d\tilde{t} \le 0$ for $\theta_0 \le |\theta| \le \pi$. It is not difficult to see that for $\theta_0 \le |\theta| \le \pi$ we have $|d\tilde{t}| \le r\, d\theta$. Now

$$|\mathrm{III}| \le \int dr \int_{\theta_0 \le |\theta| \le \pi} |g'(z)|\, |d\tilde{t}|,$$

where the integral is restricted to the region $\Delta_{\tau^{1/n}}(\alpha_{i_0,n})\setminus\Delta$. So as we know that for $\theta_0 \le |\theta| \le \pi$, $|d\tilde{t}| \le r\, d\theta$, by Schwarz's inequality,

$$\begin{aligned}
|\mathrm{III}| &\le \int dr \int_{\theta_0 \le |\theta| \le \pi} |g'(z)|\, |d\tilde{t}| \le \int dr \int_{\theta_0 \le |\theta| \le \pi} |g'(z)| r\, d\theta \\
&\le \iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})} |g'(z)| r\, dr\, d\theta \\
&\le \left\{ \iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})} |g'(z)|^2 r\, dr\, d\theta \right\}^{1/2} \left\{ \iint_{\Delta_{\tau^{1/n}}(\alpha_{i_0,n})} r\, dr\, d\theta \right\}^{1/2} \\
&\le \pi \left[\frac{p}{n} [\tau^{1/n} + |\alpha|^{1/n}]^2 \right]^{1/2}.
\end{aligned}$$

Therefore,

$$\sigma_n(1) \ge \mathrm{I} - |\mathrm{III}| \ge \iint_\Delta |g'(z)|\, d\tilde{t}\, dr - \pi \left[\frac{p}{n} [\tau^{1/n} + |\alpha|^{1/n}]^2 \right]^{1/2}.$$

Now we pass to estimate I from below, namely,

$$\mathrm{I} = \iint_\Delta |g'(z)|\, d\tilde{t}\, dr.$$

If we set $\tilde{\rho} e^{it} = 1 - re^{-i\theta}$, a calculation shows that

$$d\tilde{t}\, dr = \frac{\cos t - \tilde{\rho}}{(1 + \tilde{\rho}^2 - 2\tilde{\rho}\cos t)^{1/2}} d\tilde{\rho}\, dt.$$

Also, since $(1+\tilde{\rho}^2-2\tilde{\rho}\cos t)\le 1$ in $|z-\frac{1}{2}|\le\frac{1}{2}$, we have that

$$\begin{aligned}\sigma_n(1) &\ge \int_{-\pi/4}^{\pi/4} dt \int_{l_t\cap\Delta} \frac{|g'(z)|(\cos t-\tilde{\rho})}{(1+\tilde{\rho}^2-2\tilde{\rho}\cos t)^{1/2}}\, d\tilde{\rho} - \pi\left[\frac{p}{n}[\tau^{1/n}+|\alpha|^{1/n}]^2\right]^{1/2} \\ &\ge \int_{-\pi/4}^{\pi/4} dt \int_{l_t\cap\Delta} |g'(z)|(\cos t-\tilde{\rho})\, d\tilde{\rho} - \pi\left[\frac{p}{n}[\tau^{1/n}+|\alpha|^{1/n}]^2\right]^{1/2}.\end{aligned}$$

If we consider now $l_t/2$ to be half of the segment l_t, the half having the point $\zeta=1$ as one of its end points, then $(\cos t-\tilde{\rho})\ge\frac{\cos t}{2}$ on $[l_t/2\cap\Delta]$ for each $\frac{-\pi}{4}\le t\le\frac{\pi}{4}$, and the other end point of $l_t/2$ lies on $|z-\frac{3}{4}|=\frac{1}{4}$. Thus,

$$\sigma_n(1)\ge\int_{-\pi/4}^{\pi/4}\frac{\cos t}{2}\,dt\int_{l_t\cap\Delta}|g'(z)|\,d\tilde{\rho}-\pi\left[\frac{p}{n}[\tau^{1/n}+|\alpha|^{1/n}]^2\right]^{1/2}.$$

By our construction $[l_t/2\cap\Delta]$ contains a segment joining the point $\zeta=1$ with a boundary point of $\Delta_{\tau^{1/n}}(\alpha_{i_0,n})$, since by our choice of τ the connected component of Δ with the point $\zeta=1$ as boundary point lies inside the circle $|z-\frac{3}{4}|=\frac{1}{4}$ and one of the end points of $l_t/2$ lies on $|z-\frac{3}{4}|=\frac{1}{4}$. Therefore,

$$\int_{l_t/2\cap\Delta}|g'(z)|\,d\tilde{\rho}\ge\tau^{1/n}$$

for each $-\frac{\pi}{4}\le t\le\frac{\pi}{4}$. Hence

$$\sigma_n(1)\ge\frac{\sqrt{2}}{2}\tau^{1/n}-\pi\left[\frac{p}{n}[\tau^{1/n}+|\alpha|^{1/n}]^2\right]^{1/2},$$

and the same estimate holds for each $\zeta\in E_{i_0,n}$; therefore,

$$S_n\ge\frac{\sqrt{2}}{2}\tau^{1/n}-\pi\left[\frac{p}{n}[\tau^{1/n}+|\alpha|^{1/n}]^2\right]^{1/2}. \tag{1.4}$$

By (1.3) and (1.4)

$$\pi\left[\frac{p(\gamma(E_{i_0,n}))}{2n}\right]^{1/2}[\tau^{1/n}+|\alpha|^{1/n}]\ge S_n\ge\frac{\sqrt{2}}{2}\tau^{1/n}-\pi\left[\frac{p}{n}[\tau^{1/n}+|\alpha|^{1/n}]^2\right]^{1/2},$$

for any $n>0$. Hence we must have

$$\pi\left[\frac{p(\gamma(E_{i_0,n}))}{2n}\right]^{1/2}[\tau^{1/n}+|\alpha|^{1/n}]\ge\frac{\sqrt{2}}{2}\tau^{1/n}-\pi\left[\frac{p}{n}[\tau^{1/n}+|\alpha|^{1/n}]^2\right]^{1/2}, \tag{1.5}$$

dividing both sides by $[\tau^{1/n}+|\alpha|^{1/n}]$, we have

$$\pi\left[\frac{p(\gamma(E_{i_0,n}))}{2n}\right]^{1/2}\ge\frac{\sqrt{2}}{2}\frac{\tau^{1/n}}{[\tau^{1/n}+|\alpha|^{1/n}]}-\pi\left[\frac{p}{n}\right]^{1/2},$$

squaring both sides, taking the lim inf as $n\to\infty$, and dividing both sides by π^2p, we obtain

$$\liminf_{n\to\infty}\left[\frac{\gamma(E_{i_0,n})}{n}\right]\ge\frac{1}{4\pi^2p},$$

which proves our theorem.

As an immediate corollary to Theorem 1 we obtain an estimate in how big the size of E can be for the function $f(z)$ not to be necessarily a constant. More precisely,

Corollary 1. *Suppose that* $f(z) \in \mathrm{AMP}$ *and that*

$$f(e^{i\theta}) = \lim_{r\to 1} f(re^{i\theta}) = \alpha$$

for any $e^{i\theta} \in E$. *Then if* $\operatorname{cap}(E) > 2e^{-1/4\pi^2 p}$, *the function* $f(z)$ *is constant.*

Proof of Corollary 1. By Theorem 7.17 in [10, p. 437] we have

$$\frac{\log 2 + \gamma(E_{i_0,n})}{n} \leq \log 2 + \gamma(E) = \log\left[\frac{2}{\operatorname{cap}(E)}\right].$$

By hypothesis,

$$\frac{1}{4\pi^2 p} > \log\left[\frac{2}{\operatorname{cap}(E)}\right];$$

hence,

$$\frac{\log 2 + \gamma(E_{i_0,n})}{n} < \log\left[\frac{2}{\operatorname{cap}(E)}\right] < \frac{1}{4\pi^2 p},$$

taking the $\liminf_{n\to\infty}$ in both sides of the above inequality, we obtain

$$\liminf_{n\to\infty}\left[\frac{\gamma(E_{i_0,n})}{n}\right] < \frac{1}{4\pi^2 p},$$

which implies by Theorem 1, that the function $f(z)$ is constant, and the corollary is proved.

2. A CONSTRUCTION

In the introduction we mentioned that Riesz's theorem does not hold in full generality. In this section we are going to construct a function in AMP, nonconstant and such that it has the same nontangential limit in a set E of positive capacity.

Let $f(z)$ be the function constructed in [2]; it satisfies that $\iint_\Delta |f'(z)|^2\,dx\,dy < \infty$ and $\lim_{r\to 1} f(re^{i\theta}) = 0$ for all $e^{i\theta} \in E \subset \partial\Delta$ that $\operatorname{cap}(E) > 0$. And

If we denote by $n(w)$ the number of roots of $f(z) = w$,

$$\iint_\Delta |f'(z)|^2\,dx\,dy = \int_0^\infty \int_0^{2\pi} n(w)\,d\sigma(w) < \infty,$$

where $d\sigma(w)$ denotes the Lebesgue measure. It follows from the absolute continuity of the above integral that for almost all complex w_0 we have

$$\lim_{r\to 1} \frac{1}{\pi r^2} \iint_{|w-w_0|<r} n(w)\,d\sigma(w) \to n(w_0) < \infty. \tag{2.1}$$

Choose w_0, w_1 so that (2.1) holds for both values, and set

$$F(z) = \frac{f(z) - w_0}{f(z) - w_1}.$$

Then $F(z)$ has angular limit $\alpha = w_0/w_1$ at all points of E. Also the equations $f(z) = 0, \infty$ only have finitely many roots, since $n(w_0)$ and $n(w_1)$ are finite. We claim that $f(z) \in \mathrm{AMP}$. In fact, it follows from (2.1) that if $N(w)$ denotes the number of roots of $F(z) = w$, then

$$\int_0^{2\pi} \int_0^R N(te^{i\phi})t\,dt\,d\phi = O(R^2) \tag{2.2}$$

as $R \to 0$ and

$$\int_0^{2\pi} \int_R^{\infty} \frac{N(te^{i\phi})t\,dt\,d\phi}{t^4} = O\left(\frac{1}{R^2}\right) \tag{2.3}$$

as $R \to \infty$. This implies

$$\int_{2^p}^{2^{p+1}} \int_0^{2\pi} N(te^{i\phi})t\,dt\,d\phi \le C4^p,$$

$-\infty < p < \infty$, where C is a positive constant. We use (2.2) for $p < 0$ and (2.3) for $p \ge 0$. Suppose now that $R > 0$, and choose q such that $2^q < R \le 2^{q+1}$. Then

$$\int_0^{R} \int_0^{2\pi} N(te^{i\phi})t\,dt\,d\phi \le \sum_{p=-\infty}^{q} \int_{2^p}^{2^{p+1}} \int_0^{2^{p+1}} N(te^{i\phi})t\,dt\,d\phi$$

$$\le C \sum_{p=-\infty}^{q} 4^p = \frac{4}{3}C4^q \le \frac{4}{3}CR^2.$$

The function $F(z)$ can have a finite number of poles and zeros in Δ, but by a conformal mapping of a cut annulus Ω onto the unit disc we can construct a function without poles and zeros, if we call this new function $F(z)$ again, is an areally mean $(\frac{4C}{3\pi})$-valent function, and $F(z)$ has the same angular limit $\alpha = w_0/w_1$ in a set E of positive capacity as we wanted to show.
